

1 Energy dependence of triangular flow for identified hadrons in  
2 Au+Au collisions at  $\sqrt{s_{NN}} = 14.5 - 62.4$  GeV from the STAR  
3 experiment

6 Heavy-ion collisions create matter which is characterized by high temperature  
7 and energy density, called Quark-Gluon Plasma (QGP). One of the methods for  
8 studying the transport properties and equation of state of the created matter is  
9 the measurement of azimuthal anisotropy of particles using the Fourier expansion  
10 of the azimuthal angle with respect to the event plane. The second order Fourier  
11 coefficient  $v_2$  is called elliptic flow and is sensitive to the pressure gradients arising  
12 in the region of overlapping nuclei. The third order coefficient  $v_3$  (triangular flow)  
13 is sensitive to the fluctuations of nucleons in the initial state of colliding nuclei and  
14 therefore  $v_3$  weakly depends on the collision centrality. Theoretical studies show  
15 that  $v_3$  is more sensitive to viscous effects than  $v_2$ , making triangular flow an ideal  
16 harmonic for studying the viscosity.

17 This work is devoted to the study of triangular flow in a wide energy range  
18 of Au+Au collisions from the STAR experiment at RHIC ( $\sqrt{s_{NN}} = 14.5, 19.6, 27,$   
19  $39, 62.4$  GeV). New measurements of triangular flow will be presented as a function  
20 of particle transverse momenta ( $p_T$ ) and collision energy. Physics implications will  
21 be discussed.
