Measurements of W and Z/γ^* cross sections and their ratios in pp collisions at STAR

Jae D. Nam, for the STAR collaboration

January 28, 2021

While the unpolarized valence quark (d and u) distributions are well determined from DIS experiments, the sea quark counterparts, $\bar{d}$ and $\bar{u}$, are much less constrained, in particular, near the valence region. Measurements of W^+/W^- production ratio in pp collider experiments, such as the STAR experiment at RHIC, are sensitive to the $\bar{d}/\bar{u}$ ratio at leading order at a large Q^2 set by the W mass. This talk will discuss the recently published W and Z/γ^* cross section measurements via lepton-decay tagging, using the STAR pp collision data at a center-of-mass energy of $\sqrt{s} = 510\,\text{GeV}$ collected during the years 2011-2013, corresponding to an integrated luminosity of $350\,\text{pb}^{-1}$. A status update will be given on an analysis based on an additional data set at $\sqrt{s} = 510\,\text{GeV}$ collected in 2017, corresponding to an integrated luminosity of $350\,\text{pb}^{-1}$.
