

# Quarkonia in STAR

Grazyna Odyniec for the **STAR** Collaboration  
Lawrence Berkeley National Laboratory

## Outline :

Why quarkonium?

STAR @ RHIC

$J/\psi$  results

$\Upsilon$  results

outlook

# Why quarkonia ?

Classic signature of quark-gluon plasma formation:

charm & bottom quarks produced in the initial hard parton-parton scattering (large mass) at RHIC

→ present through evolution of collision → excellent tool to study properties of QGP

signature of deconfinement : suppression of  $J/\psi$  due to the screening of the binding potential between c and c-bar quarks in QGP

*T.Matsui, H.Satz, Phys.Lett. B 178, 416 (1986)*

also recent lattice calculations:

*A.Mocsy and P.Petreczky, Phys.Rev.Lett.99, 211602 (2007), arXiv:0706.2183,  
Phys.Rev.D 77,014501 (2008), arXiv:0705.2559*

# Quarkonia: - QGP Thermometer

With increasing temperature the different quarkonium states “melt” sequentially as a function of their binding strength: the most loosely bound state disappears first, the ground state last

Suppression of states is determined by  $T_c$  and their binding energy

Dissociation points of the different quarkonium states provide a way to measure the temperature of the medium

# J/ψ suppression at SPS ~ J/ψ suppression at RHIC

a new mechanism at RHIC ?

## suppression vs. regeneration

*P. Braun-Munzinger and J. Stachel, Phys. Lett. B490,196 (2000); L. Grandchamp and R. Rapp, Phys. Lett. B523, 60 (2001); M. I. Gorenstein et al., Phys. Lett. B524, 265 (2002); R. L. Thews, M. Schroedter, and J. Rafelski, Phys. Rev. C63, 054905 (2001); Yan, Zhang and Xu, Phys.Rev.Lett.97, 232301 (2006);*

## sequential melting of charmonia states

*F. Karsch, D. Kharzeev and H. Satz, PLB 637, 75 (2006); B. Alessandro et al. (NA50), Eur. Phys. J. C 39 (2005) 335; H. Satz, Nucl. Phys. A (783):249-260(2007)*

Need to understand: fraction of direct production

- decay feed-down from B and  $\chi_c$  states
- gluon and heavy quark fragmentation
- color screening
- recombination
- comover and cold matter effects
- energy loss ...

Production of quarkonia is complex and there is no convincing model, so far, even for p+p → need detailed study (p+p, p+A, A+A)

# Relativistic Heavy Ion Collider (RHIC)

Brookhaven National Laboratory (BNL), Upton, NY

# STAR Detector

Large acceptance: full  $2\pi$  coverage at mid-rapidity

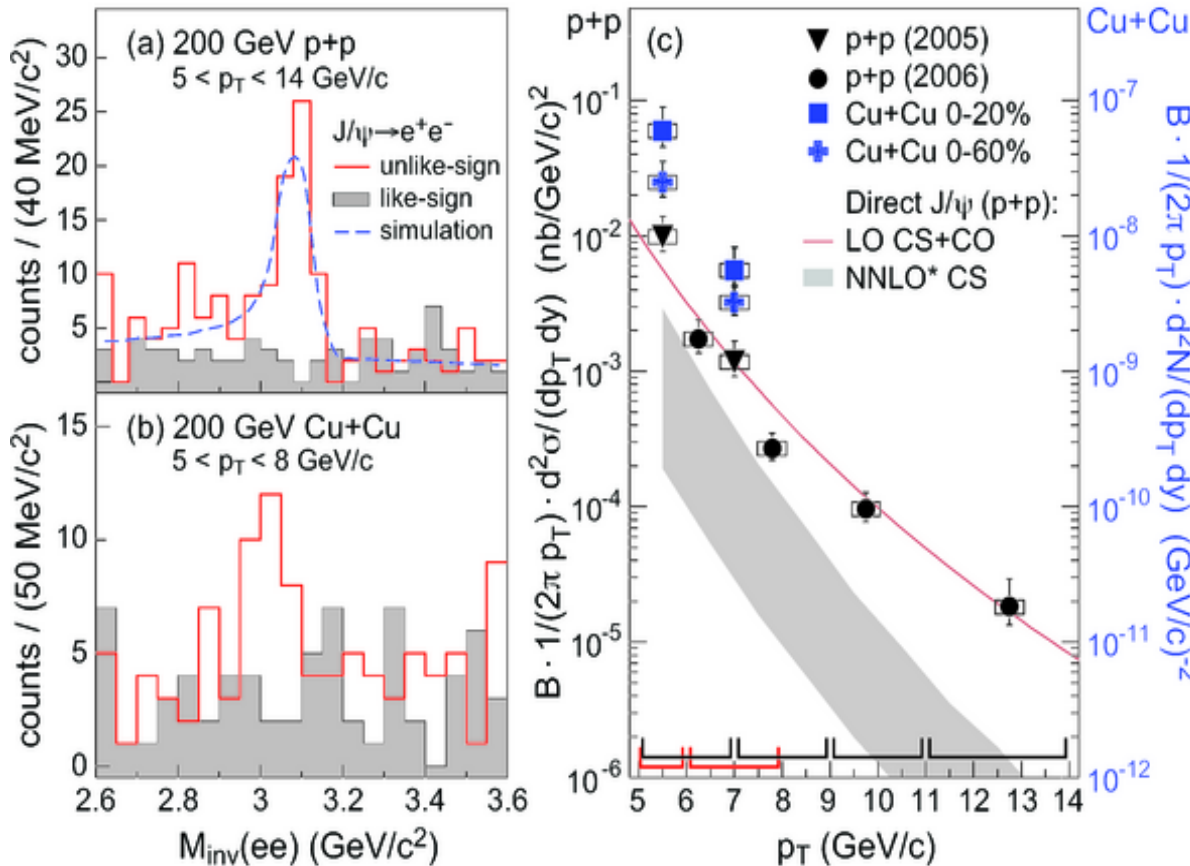

STAR data :

- p+p ( $J/\psi$ ,  $\Upsilon$ )
- d+Au ( $J/\psi$ ,  $\Upsilon$ )
- Cu+Cu ( $J/\psi$ )
- Au+Au ( $J/\psi$ ,  $\Upsilon$ )

# J/ψ (p<sub>t</sub> > 5 GeV) in p+p and Cu+Cu at 200 GeV

Phys.Rev.C80:041902,2009 (STAR)

J/ψ → e<sup>+</sup>e<sup>-</sup> (5.9 %)

NRQCD (LO CO+CS) – describes data well, but no room for feed down from  $\psi'$ ,  $\chi_c$ , B  
 G. C. Nayak, M. X. Liu, and F. Cooper, Phys. Rev. D68, 034003 (2003), and private communication

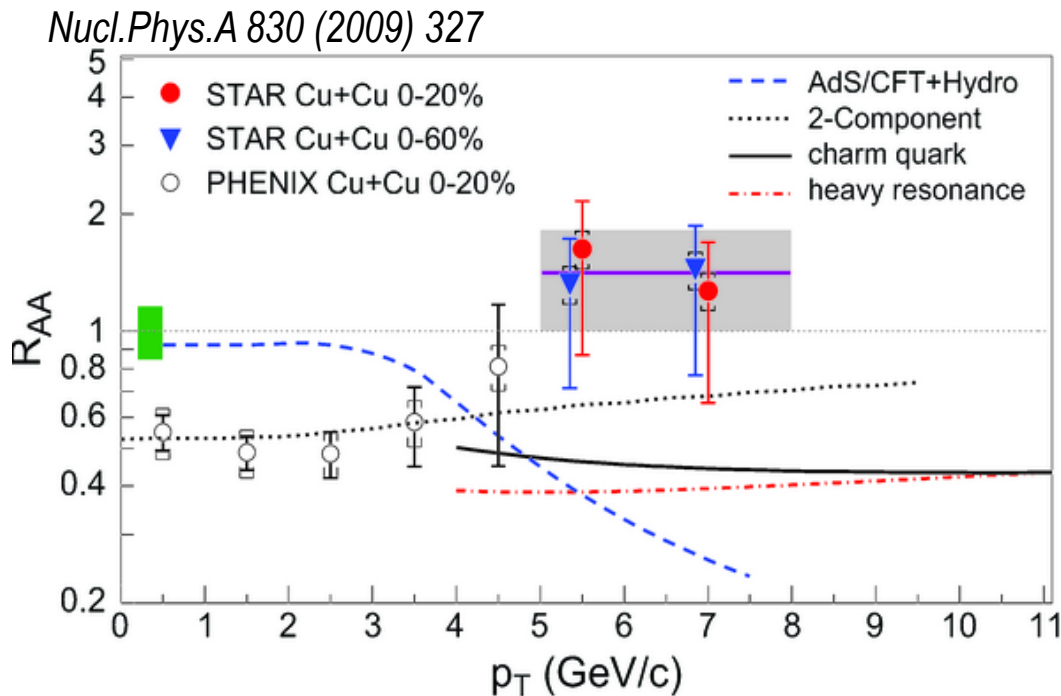

NNLO CS predicts a steeper p<sub>t</sub> dependence  
 P. Artoisenet et al., Phys. Rev. Lett. 101, 152001 (2008), and J.P. Lansberg private communication

No feed down included in models (estimated to be a factor of ~1.5)

Can we constraint the B feed-down through other observables ?

$$R_{AA}(p_T) = \frac{d^2 N^{AA} / dp_T d\eta}{T_{AA} d^2 \sigma^{NN} / dp_T d\eta}$$

## Nuclear modification factor $R_{AA}^{\text{Cu+Cu}}$ at high- $p_{\perp}$

$R_{AA}^{\text{Cu+Cu}}$  is rising towards unity  
for  $> 5$  GeV (but uncertainty !)

- no suppression at high  $p_{\perp}$

$$R_{AA}(p_{\perp} > 5 \text{ GeV}/c) = 1.4 \pm 0.4 \pm 0.2$$

$J/\psi$  is the only hadron measured in RHIC HI collisions that does not exhibit significant  $p_{\perp}$  suppression

In contrast to strong suppression of open charm *B.Abedev et al., Phys.Rev.Lett. 98 (2007), 192301, S.Adler et al., Phys.Rev.Lett. 96(2006) 032301.*

Two Component Model (including: color screening, stat.coalescence, B feed-down, formation time) describes data *X. Zhao and R. Rapp (2007), arXiv:0712.2407; Y.P. Liu, et al., Phys.Lett.B678:72-76,2009*

Contradicts AdS/CFT+ Hydro prediction (99% C.L.)

*H. Liu, K. Rajagopal and U.A. Wiedemann PRL 98, 182301(2007); T. Gunji, J. Phys.G 35, 104137 (2008)*

# Constraining bottom yields

## $J/\psi$ -h azimuthal correlation

Phys.Rev.C80:041902,2009 (STAR), arXiv:0904.0439 (STAR)

pQCD predicts significant  $B \rightarrow J/\psi$   
correlation shows a low B contribution (13 +/- 5)% at  $p_t > 5 \text{ GeV}$   
can be used to further constrain B yields

# Understanding $J/\psi$ production mechanism

- $p+p$  baseline

currently all models have difficulty simultaneously reproducing quarkonia cross section,  $p_t$  and polarization

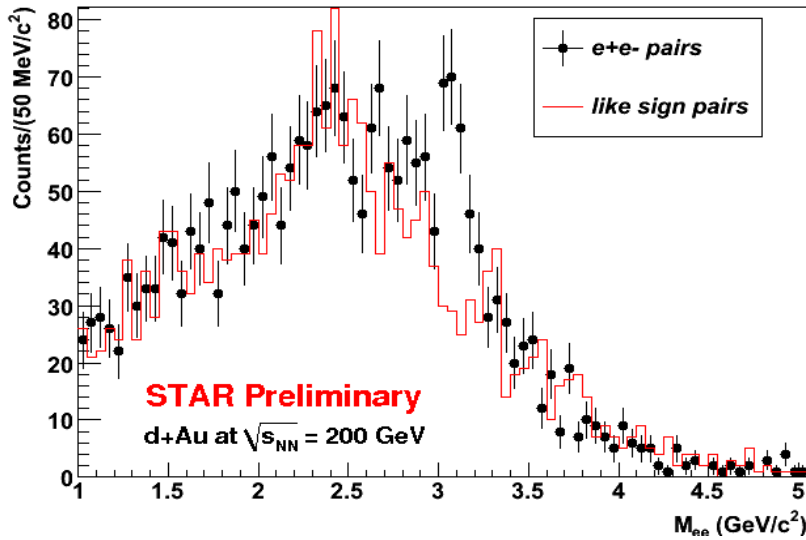

- $d+Au$  important (cold nuclear matter effects)

- initial state energy loss
- gluon shadowing
- Cronin effect
- nuclear absorption

# Low- $p_t$ $J/\psi$ in d+Au, Run 8 (no inner silicon detector)

Signal, all centralities.

Invariant mass spectrum for electron pairs

Like-sign subtracted

$\chi^2 / \text{ndf}$  78.57 / 79  
N  $55.31 \pm 7.93$

Corrected, 0-20% most central

$R_{dAu}$ : consistent with  $N_{bin}$  scaling

# Bottomonia

More of the same ?

**NO !**

$\Upsilon$  is a much cleaner probe of high-temperature color screening

→ sequential disappearance of states (QCD thermometer):

at 200 GeV :  $\Upsilon(1S)$  does not melt

$\Upsilon(2S)$  is likely to melt

$\Upsilon(3S)$  will melt A.Mocsy, P.Petraczky PRD 77 014501 (2008)

Co-mover absorption is very small Phys.Lett.B 503, 104 (2001)

Less problems with feed-down (compare to  $J/\psi$ )

Recombination negligible at RHIC Phys.Rev.Lett. 95, 122001 (2005)

(... and it will complicate the picture at LHC)

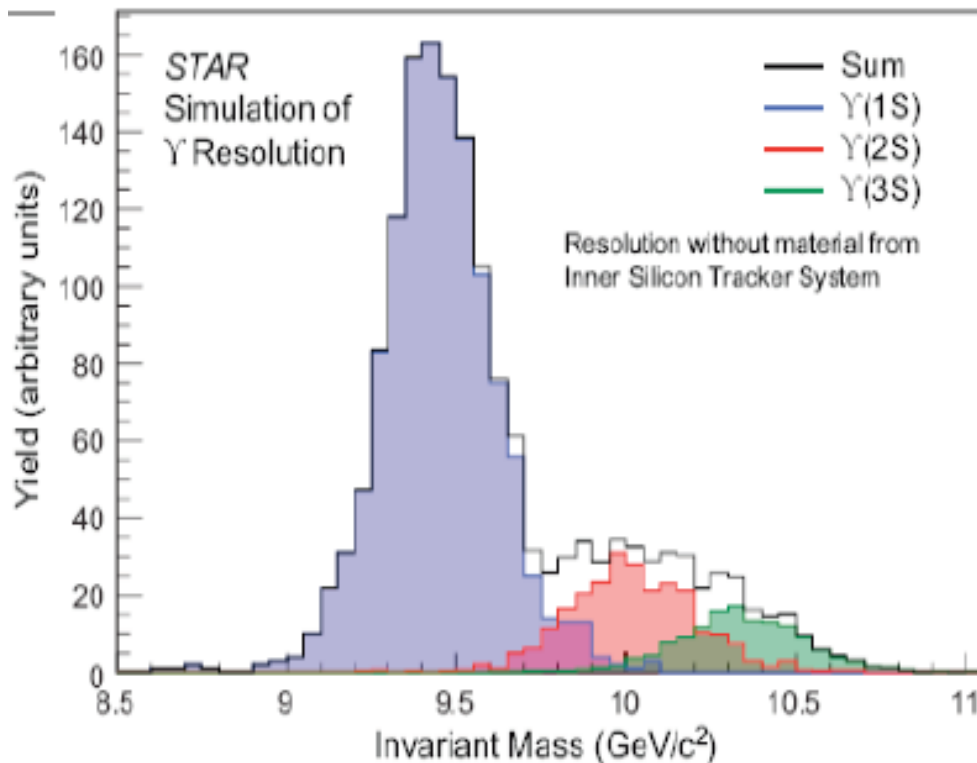

# $\Upsilon$ (1S+2S+3S)

Branching fractions for  $\Upsilon(nS) \rightarrow e^+e^-$  Phys. Lett. B 667, 1 (2008)

$\Upsilon$ state	$B$ (%)	$\sigma$ (nb)
$\Upsilon(1S)$	$2.38 \pm 0.11$	6.60
$\Upsilon(2S)$	$1.91 \pm 0.16$	2.18
$\Upsilon(3S)$	$2.18 \pm 0.21$	1.32

extremely low rate:  
 $10^{-9}$ /min.bias pp collision (3 orders of magnitude smaller than  $\sigma_{J/\psi}$ )

Phys.Rep. 462, 125 (2008)

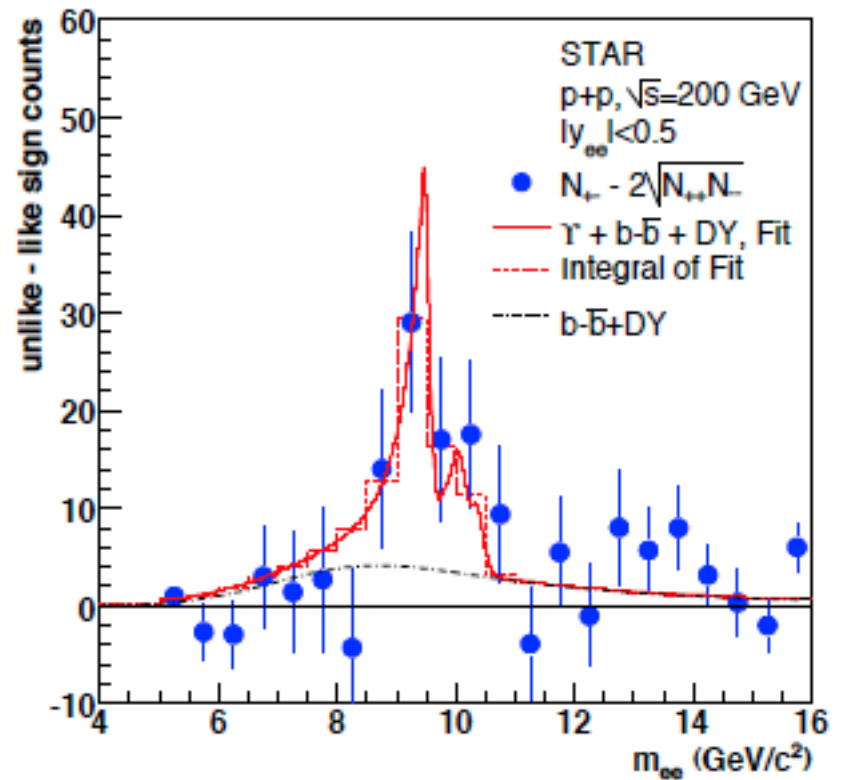

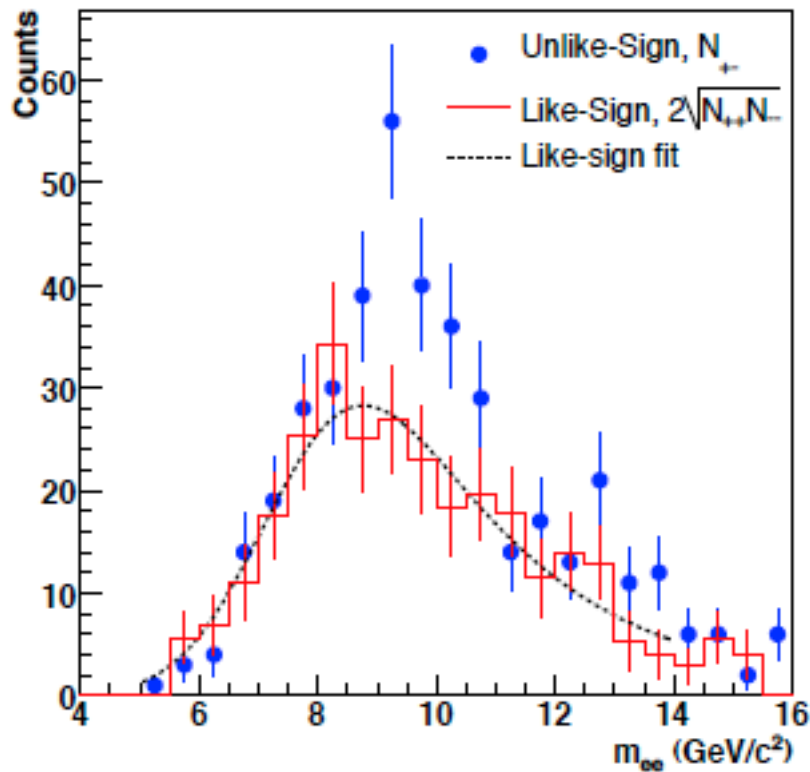

$\Upsilon$  (1S+2S+3S) separation ?

requires a high resolution :  
Run 2006 (pp), 2007(AuAu) – large material budget

Run 2008 (dAu), 2009 (pp), 2010 (AuAu)  
- small material budget – separation possible

# First $\Upsilon(nS)$ from p+p @ 200 GeV

e-preprint: nucl-ex 1001.2745

$$\sum_{n=1}^3 B(nS) \times \sigma(nS) = 114 \pm 38 + 23 / - 24 \text{ pb}$$

# STAR $\Upsilon$ ( $nS$ ) in pp vs theory and world data

arXiv:1001.27451

STAR  $\Upsilon$  in p+p at 200 GeV at mid-rapidity is consistent with CEM at NLO (inconsistent with CSM:  $\sim 2\sigma$ )

Consistent with world data trend

# $\Upsilon$ in d+Au

Nucl.Phys. A830 (2009) 235, , nucl-ex 0907.4538

$\Upsilon(1S+2S+3S)$  total yield: integrated from 7 to 11 GeV from background-subtracted  $m_{ee}$  distribution

raw yield:  $172 \pm 20$  (stat.)

strong signal,  $8\sigma$  significance (no SVT, "low mass run")

Grazyna Odyniec

DIS 2010, Florence, Italy, April 2010

# STAR $\Upsilon$ ( $nS$ ) in dAu vs theory

arXiv:0907.4538

$$\sum_{n=1}^3 B(nS) \times \sigma(nS) = 34 \pm 4 \pm 5 \text{ nb}$$

$$R_{\text{dAu}} = 0.98 \pm 0.32(\text{stat.}) \pm 0.28(\text{sys.})$$

CNM effects (shadowing) are small, need more pp statistics to quantify the effect ( $\sim$  consistent with  $N_{\text{bin}}$  scaling)

# $\Upsilon$ ( $nS$ ) in Au+Au

Animation: Manuel Calderón de la Barca Sánchez

Au+Au, 200 GeV STAR upsilon event - **analysis in progress !!!**

*Grazyna Odyniec*

---

# Summary and Future

## *J/ψ* spectra in 200 GeV p+p collisions in STAR:

extended pt range up to ~14 GeV/c  
spectra can be described by CEM and CSM  
azimuthal correlations constrain B contribution

## *J/ψ* in Cu+Cu high $p_t$ :

$R_{AA}$  increases at high  $p_t$  ( $p_t > 5$  GeV)

## $\Upsilon + \Upsilon' + \Upsilon'' \rightarrow e+e-$ cross-section at $\sqrt{s}=200$ GeV:

p+p :  $B \times (d\sigma/dy) = 114 \pm 38(\text{stat}) \pm 23/24(\text{sys})$  pb

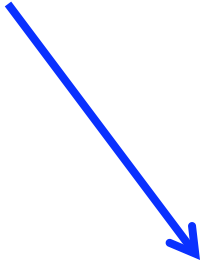

d+Au :  $B \times (d\sigma/dy) = 35 \pm 4(\text{stat}) \pm 5(\text{sys})$  nb

$R_{dAu} = 0.98 \pm 0.32(\text{stat}) \pm 0.28(\text{sys})$

consistent with binary scaling

good reference for QGP effects

Au+Au (central 0-60%) – analysis in progress

Analysis of low material run are in progress (pp, 200 GeV - run 9, AuAu, 200 GeV - run 10).  
May allow separation 1S,2S,3S states.

thank you!

# $\Upsilon$ Trigger in STAR

arXiv:1001.2745

L0 – fast hardware trigger:

$$E_T > E_t^{\text{threshold}}$$

L2 – software trigger:

$$E_T^{(\text{cl.1})} > E_T^{\text{thershold1}}, E_T^{(\text{cl.2})} > E_T^{\text{thershold2}},$$

Calculate:  $\cos\theta$

$$m^{(\text{cl1-cl2})} = 2\sqrt{E^{\text{cl1}} E^{\text{cl2}} (1 - \cos\theta)}$$

$$m^{(\text{cl1-cl2})} > m^{\text{threshold}} ?$$

Decision in  $\sim 5$  ms for slow detectors to keep / abort data

# Modification Factor $R_{AA}$

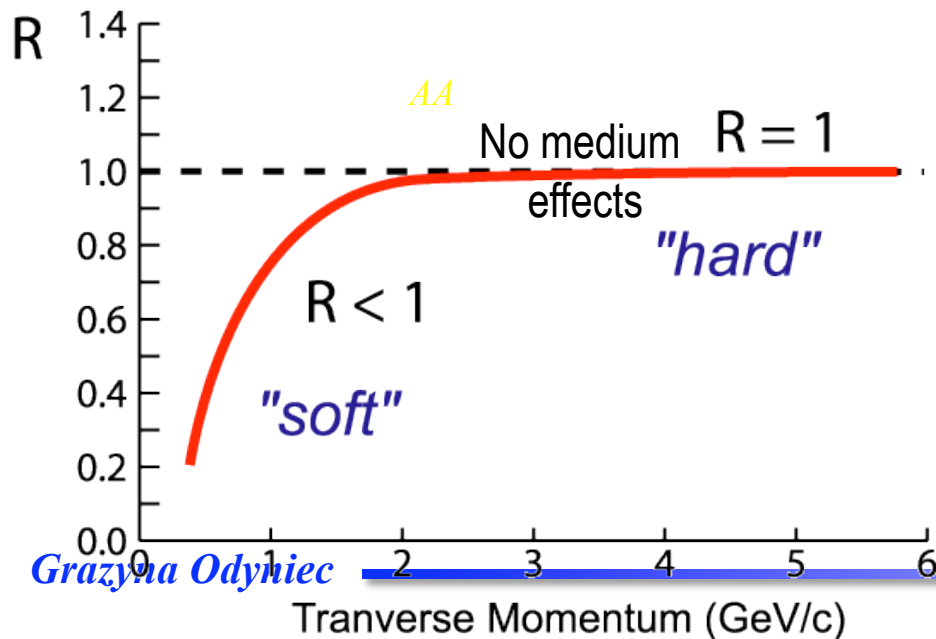

1. Compare Au+Au to nucleon-nucleon cross sections
2. Compare Au+Au central/peripheral

Nuclear Modification Factor:  $R_{AA}$

$$R_{AA}(p_T) = \frac{d^2 N^{AA} / dp_T d\eta}{T_{AA} d^2 \sigma^{NN} / dp_T d\eta}$$

nucleon-nucleon cross section

$\langle N_{\text{binary}} \rangle / \sigma_{\text{inel}}^{p+p}$

If no "effects":

$R_{AA} < 1$  in regime of soft physics

$R_{AA} = 1$  at high- $p_T$  where hard scattering dominates

Suppression:

$R_{AA} < 1$  at high- $p_T$

# $\Upsilon$ (nS) in Au+Au

some info  
about upsilon  
trigger ?

Au+Au, 200 GeV  
STAR upsilon event

analysis in  
progress !!

# # 1: $R_{\text{AuAu}} (y \approx 0 @ \text{RHIC}) \approx R_{\text{PbPb}} (@ \text{SPS})$

RHIC: PRL98 (2007) 232301, SPS: from Scomparin @ QM06

- At mid- $y$   $R_{\text{AA}}$  looks similar, while there are obvious differences:
  - at a given  $N_{\text{part}}$ , at RHIC much higher energy densities...
  - cold nuclear matter effects should be drastically different ( $X_{\text{Bjorken}}, \sigma_{\text{abs}} \dots$ )
  - ...

# The STAR Detector
