Science

# Motivation

J. Adam et al. (STAR Collaboration), Phys. Rev. Lett. 123, 132302.

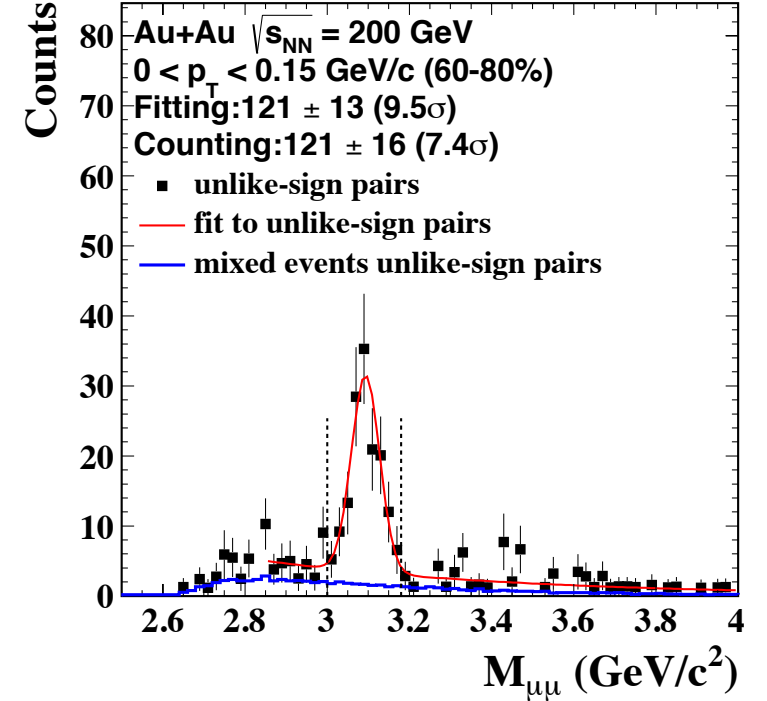

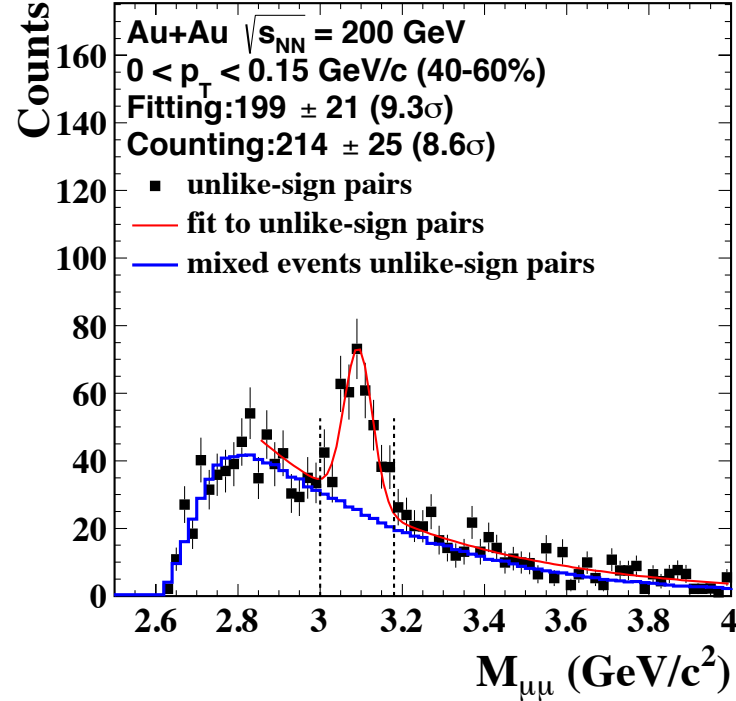

- Significant enhancements of the  $J/\psi$  production via  $e^+e^-$  decay channel **at very low  $p_T$**  observed by the STAR collaboration in peripheral Au+Au 200 GeV and U+U 193 GeV collisions.
  - Much weaker centrality dependence compared to the hadronic production.
  - Consistent with **coherent photon-nucleus interactions**.
- Measurement of  $J/\psi$  production via  $\mu^+\mu^-$  decay channel can provide complementary information to the previous dielectron results.

# The STAR detector and raw signal extraction

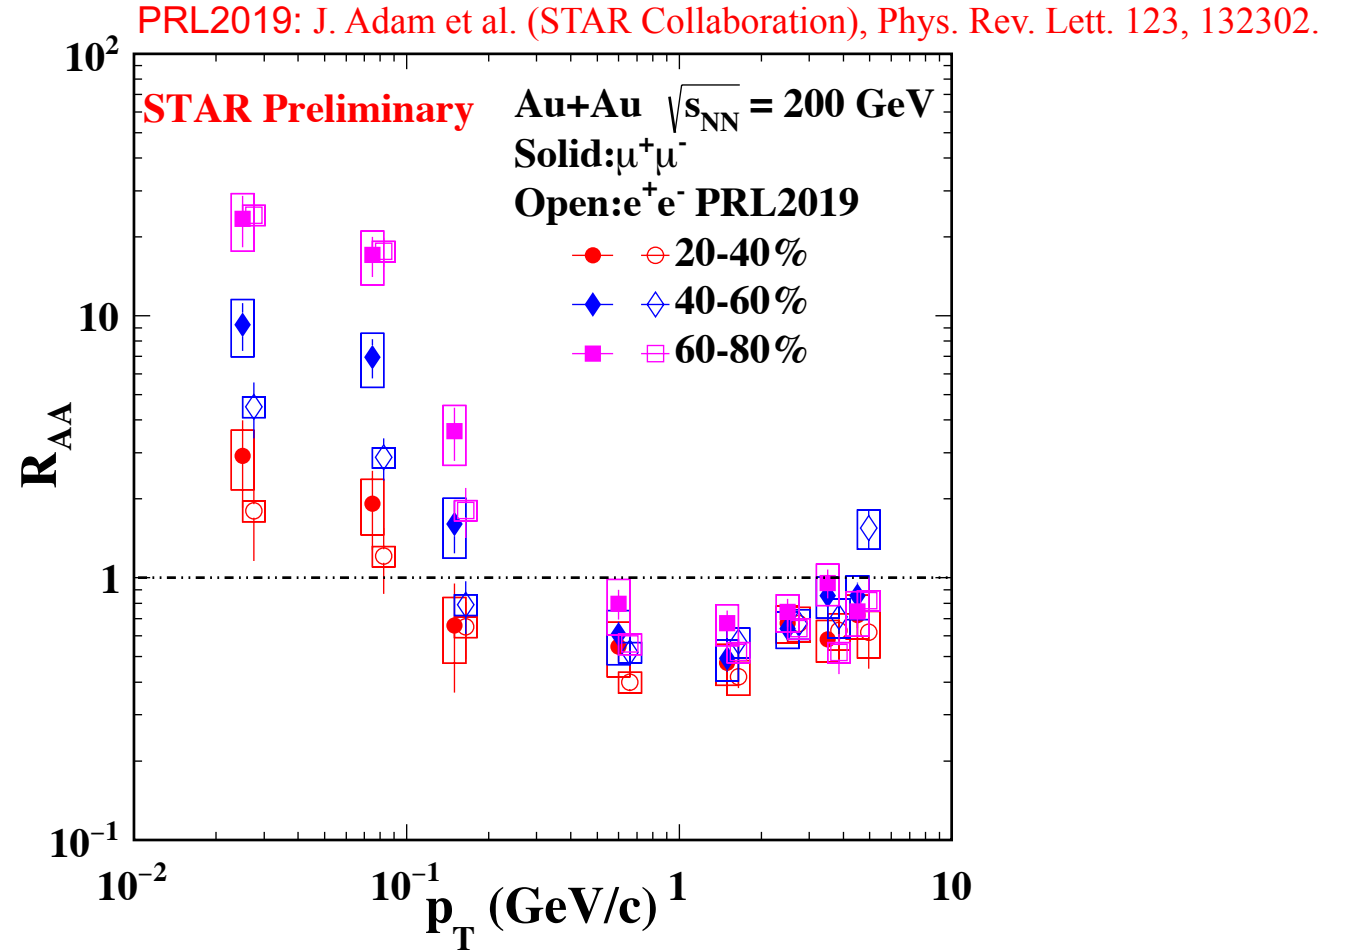

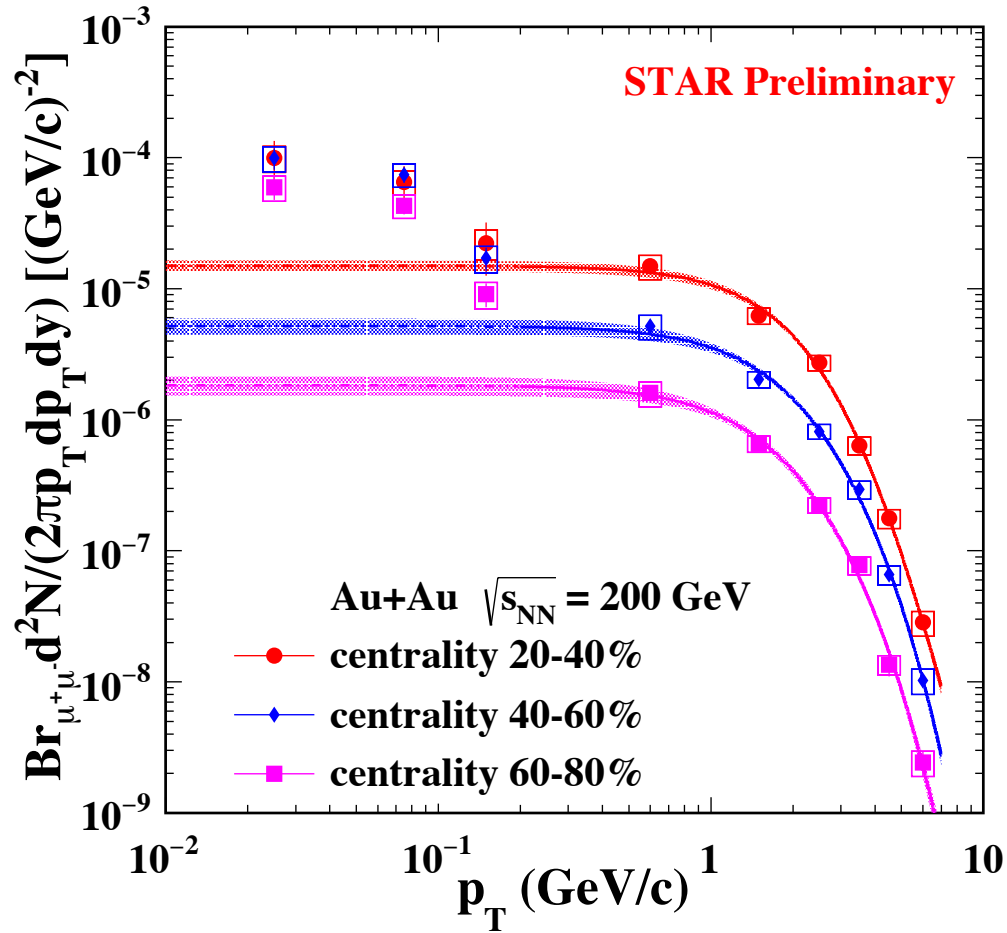

TPC : track reconstruction and particle identification.  
( full  $\phi$  coverage,  $|\eta| < 1$ )  
MTD : triggering on and identifying muons  
( 45% in  $\phi$ ,  $|\eta| < 0.5$ )

- Dataset : Au+Au collisions at  $\sqrt{s_{NN}} = 200$  GeV in 2014, dimuon trigger.
- Maximum Likelihood method is used for raw signal extraction.

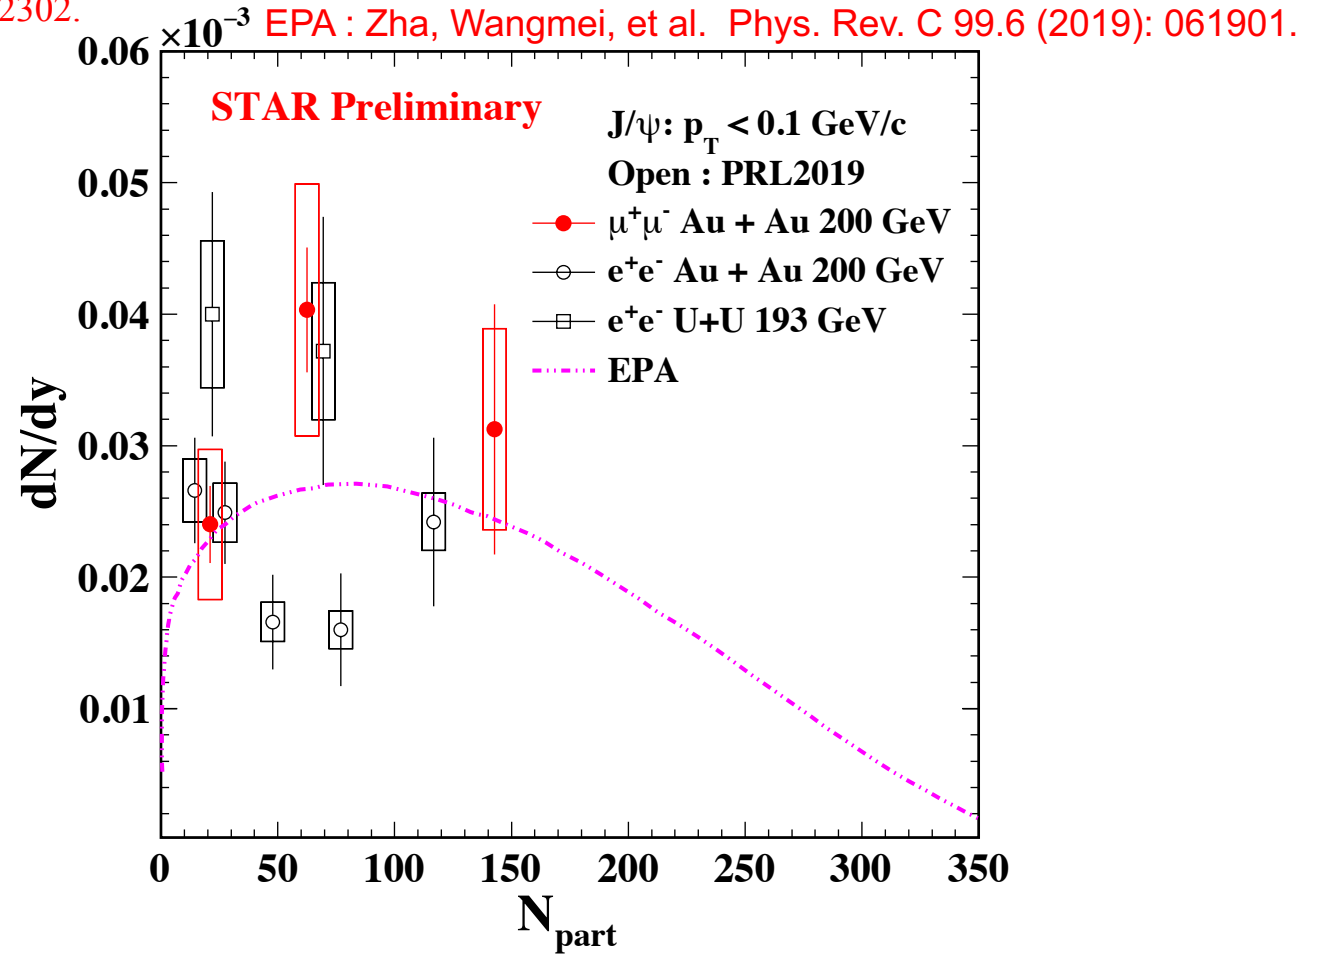

# Invariant yield and $R_{AA}$

- Significant enhancement at  $p_T < 0.2 \text{ GeV/c}$  is observed for  $J/\psi$  production with respect to the extrapolation of fit of data for  $p_T > 0.2 \text{ GeV/c}$ , which is reflected in a large enhancement of  $R_{AA}$  above unity.

# $p_T^2$ distribution and excess yield

PRL2019: J. Adam et al. (STAR Collaboration), Phys. Rev. Lett. 123, 132302.

- An exponential fit is applied to the  $-t$  distribution, and the slope parameter is  $153 \pm 55$   $(GeV/c)^{-2}$ , consistent with that expected for an Au nucleus [ $199$   $(GeV/c)^{-2}$ ] within uncertainties. The slope parameter is  $177 \pm 23$   $(GeV/c)^{-2}$  from published results via  $e^+e^-$  channel.
- Excess yield consistent with equivalent photon approximation (EPA) calculation.
